Short title: Integrative models of NuRD sub-complexes

Abstract

The Nucleosome Remodeling and Deacetylase (NuRD) complex is a chromatin-modifying assembly that regulates gene expression and DNA damage repair. Despite its importance, limited structural information is available on the complex and a detailed understanding of its mechanism is lacking. We investigated the molecular architecture of three NuRD sub-complexes: MTA1-HDAC1-RBBP4 (MHR), MTA1^N-HDAC1-MBD3^{GATAD2CC} (MHM), and MTA1-HDAC1-RBBP4-MBD3-GATAD2 (NuDe) using Bayesian integrative structure determination with IMP (Integrative Modeling Platform), drawing on information from SEC-MALLS, DIA-MS, XLMS, negative-stain EM, X-ray crystallography, NMR spectroscopy, secondary structure and homology predictions. The structures were corroborated by independent cryo-EM maps, biochemical assays, and known cancer-associated mutations. MBD3 is a demethylase that connects the deacetylase and chromatin-remodeling modules in NuRD. Localization of the full-length MBD3 in NuRD was not previously characterized. Our models indicate two different localizations for MBD3 in NuRD, suggesting a mechanism by which MBD3 in the presence of GATAD2 asymmetrically bridges the two modules in NuRD. Further, our models indicate three previously unrecognized subunit interfaces in NuDe: HDAC1^C-MTA1^{BAH}, MTA1^{BAH}-MBD3, and HDAC1$^{60-100}$-MBD3. We observed that a significant number of cancer-associated mutations mapped to protein-protein interfaces in NuDe. Our approach also allows us to localize regions of unknown structure, such as HDAC1^C and MBD3^{IDR}, thereby resulting in the most complete structural characterization of these NuRD sub-complexes so far.

Introduction

The Nucleosome Remodeling and Deacetylase (NuRD) complex is a multi-protein chromatin-modifying assembly, expressed in most metazoan tissues, and conserved across multi-cellular animals (Basta and Rauchman, 2017; Denslow and Wade, 2007; Lejon et al., 2011; Yoshida et al., 2008). It regulates gene expression and DNA damage repair and It modulates nucleosome accessibility in enhancers and promoters for transcription factors and RNA polymerases, thereby regulating the expression of target genes (Basta and Rauchman, 2017, 2015; Bornelöv et al., 2018; Burgold et al., 2019; Denslow and Wade, 2007; Li and Kumar, 2010; Reynolds et al., 2013; Smeenk et al., 2010; Yoshida et al., 2008). Subunits of NuRD are implicated in human cancers and various congenital defects (Basta and Rauchman, 2015; Toh and Nicolson, 2009). Considerable diversity is observed in subunit isoforms and NuRD-associated factors across tissues (Burgold et al., 2019; Denslow and Wade, 2007; Hoffmann and Spengler, 2019).

NuRD comprises two catalytic modules – a histone deacetylase module and ATP-dependent chromatin-remodeling module (Burgold et al., 2019; Denslow and Wade, 2007; Low et al., 2020). The deacetylase module contains metastasis-associated proteins (MTA1/2/3) that form a dimeric scaffold for the histone deacetylases (HDAC1/2). It also contains the chaperones RBBP4/7, which mediate interactions of NuRD with histone tails and transcription factors (Basta and Rauchman, 2017, 2015; Hong et al., 2005). The chromatin-remodeling module contains methyl-CpG DNA-binding proteins (MBD2/3) that recruit NuRD to methylated and/or hemi-methylated DNA, GATA-type zinc-finger proteins (GATAD2A/B), and an ATP-dependent DNA translocase (CHD3/4/5) (Burgold et al., 2019; Low et al., 2020).

Some structural information is available for the complex. Several attempts made to determine the stoichiometry of the endogenous NuRD complex have returned variable results (Bode et al., 2016; Guo et al., 2019; Kloet et al., 2015; Sharifi Tabar et al., 2019; Smits et al., 2013; Spruijt et al., 2016; Zhang et al., 2016). A recent characterization by quantitative mass

76 spectrometry from (Low et al., 2020) reported a 2:2:4:1:1:1
77 (MTA1:HDAC1:RBBP4:MBD3:GATAD2A:CHD4) stoichiometry for the full NuRD complex.
78 Atomic structures of parts of the NuRD complex, including the MTA1-HDAC1 dimer, RBBP4
79 bound to MTA1, the MBD domain of MBD3, and the coiled-coil dimer of MBD2 and GATAD2A
80 have been determined by X-ray crystallography and NMR spectroscopy (Alqarni et al., 2014;
81 Cramer et al., 2014; Gnanapragasam et al., 2011; Millard et al., 2016, 2013). Structures of the
82 2:2 MTA1-HDAC1 dimer, the 2:2:4 MTA1-HDAC1-RBBP4 complex (MHR), the 2:2:2 MTA1^N-
83 HDAC1-MBD3^{GATAD2CC} (MHM) complex, the 2:2:4:1:1 MTA1-HDAC1-RBBP4-MBD3-GATAD2
84 (NuDe complex), and CHD4 bound to a nucleosome substrate have also been characterized
85 at various resolutions by negative stain and/or cryo-electron microscopy (Farnung et al., 2020;
86 Low et al., 2020; Millard et al., 2020, 2016).
87
88 Pairwise interactions between domains and subunits within the MHR, MHM, NuDe, and the
89 endogenous NuRD complexes have also been characterized by chemical crosslinking and
90 mass spectrometry (XLMS) (Low et al., 2020; Millard et al., 2016). A model of the MHM
91 complex, based on crosslinks-driven rigid-body docking of known atomic structures with a pair
92 of MTA1-RBBP4 structures manually placed, has also been reported (Low et al., 2020). While
93 this represents the most complete model of NuRD architecture, it only accounts for 30% of
94 residues in the NuRD complex. In fact, only 50% of residues in NuRD have known or readily
95 modeled atomic structures, and the structures of proteins such as MBD3, CHD4, and GATAD2
96 are largely uncharacterized. More recent artificial intelligence-based methods such as
97 AlphaFold are also unable to resolve these uncharacterized regions (Jumper et al., 2021).
98 Owing to variability in the paralogue composition as well as significant structural dynamics, the
99 atomic structure of the entire NuRD complex is still undetermined and is likely to remain a
100 challenge for some time to come.
101
102 The 2:2:4 MTA1-HDAC1-RBBP4 complex (MHR) forms the deacetylase core of NuRD. MBD3
103 binds to the N-terminal half of MTA1 to form a 2:2:2 MTA1^N-HDAC1-MBD3^{GATAD2CC} (MHM)
104 complex, which contains two copies of MBD3 (Low et al., 2020). However, the 2:2:4:1:1 MTA1-
105 HDAC1-RBBP4-MBD3$^-$GATAD2 (NuDe complex) and the endogenous NuRD complex are
106 asymmetric, both containing a single copy of MBD3 (Low et al., 2020). The mechanism by
107 which this asymmetry is introduced in NuDe/NuRD is not known. The structure of full-length
108 MBD3 is unknown and it contains a significant intrinsically disordered region (IDR; MBD3$^{71-213}$),
109 which has been shown to be critical for recruiting the deacetylase core in case of MBD2 (Desai
110 et al., 2015). The localization of full-length MBD3 in NuDe/NuRD is also not known.

111 Here, we investigated the molecular architecture of the MHR, MHM, and NuDe complexes
112 using an integrative approach. Integrative structure determination is a method for investigating
113 structures of large assemblies which are refractory to a single experimental method such as X-
114 ray crystallography or cryo-electron microscopy (Alber et al., 2007; Ganesan et al., 2020;
115 Gutierrez et al., 2020; Kim et al., 2018; Rout and Sali, 2019; Russel et al., 2012; Viswanath et
116 al., 2017a; Ward et al., 2013). Using Bayesian integrative modeling with the Integrative
117 Modeling Platform (IMP), we combined data from complementary experiments, physical
118 principles, statistical inference, and prior models. This approach allowed us to combine noisy,
119 sparse, ambiguous, and incoherent data at various resolutions (Alber et al., 2007; Rieping et
120 al., 2005; Rout and Sali, 2019; Schneidman-Duhovny et al., 2014). It produced an ensemble of

121 models consistent with the input information, allowing us to obtain precise uncertainty bounds
122 on the structure (Saltzberg et al., 2019, 2021; Viswanath et al., 2017b; Webb et al., 2018). We
123 used data from SEC-MALLS, DIA-MS, XLMS, negative stain EM, X-ray crystallography, NMR
124 spectroscopy, secondary structure and homology predictions, and stereochemistry
125 considerations (Alqarni et al., 2014; Connelly et al., 2006; Cramer et al., 2014; Gnanapragasam
126 et al., 2011; Low et al., 2020; Millard et al., 2016, 2013). These integrative structures were
127 corroborated by independent cryo-EM maps, biochemical assays, and known cancer-
128 associated mutations, a significant number of which mapped to protein-protein interfaces in the
129 structures (Desai et al., 2015; Forbes et al., 2006; Millard et al., 2020; Pflum et al., 2001; Zhang
130 et al., 1999). By using all available information, the accuracy, precision, completeness, and
131 efficiency of structure determination were maximized (Alber et al., 2007; Rout and Sali, 2019;
132 Russel et al., 2012).

133 The integrative approach allows for regions of unknown structure to be modeled in the context
134 of regions of known structure. This facilitated the modeling of NuRD proteins with significant
135 regions of unknown structure, such as MBD3, at full-length, for the first time. Our models
136 indicate that MBD3 localizes in two different sites in NuRD. This suggests a mechanism by
137 which MBD3, in the presence of GATAD2, asymmetrically bridges the deacetylase and
138 chromatin-remodeling modules. Finally, our models enable us to compare the structure of the
139 MHR complex in the presence and absence of MBD3 and GATAD2. We show that, while the
140 MHR complex alone is dynamic, the presence of MBD3 and GATAD2 makes it less dynamic.
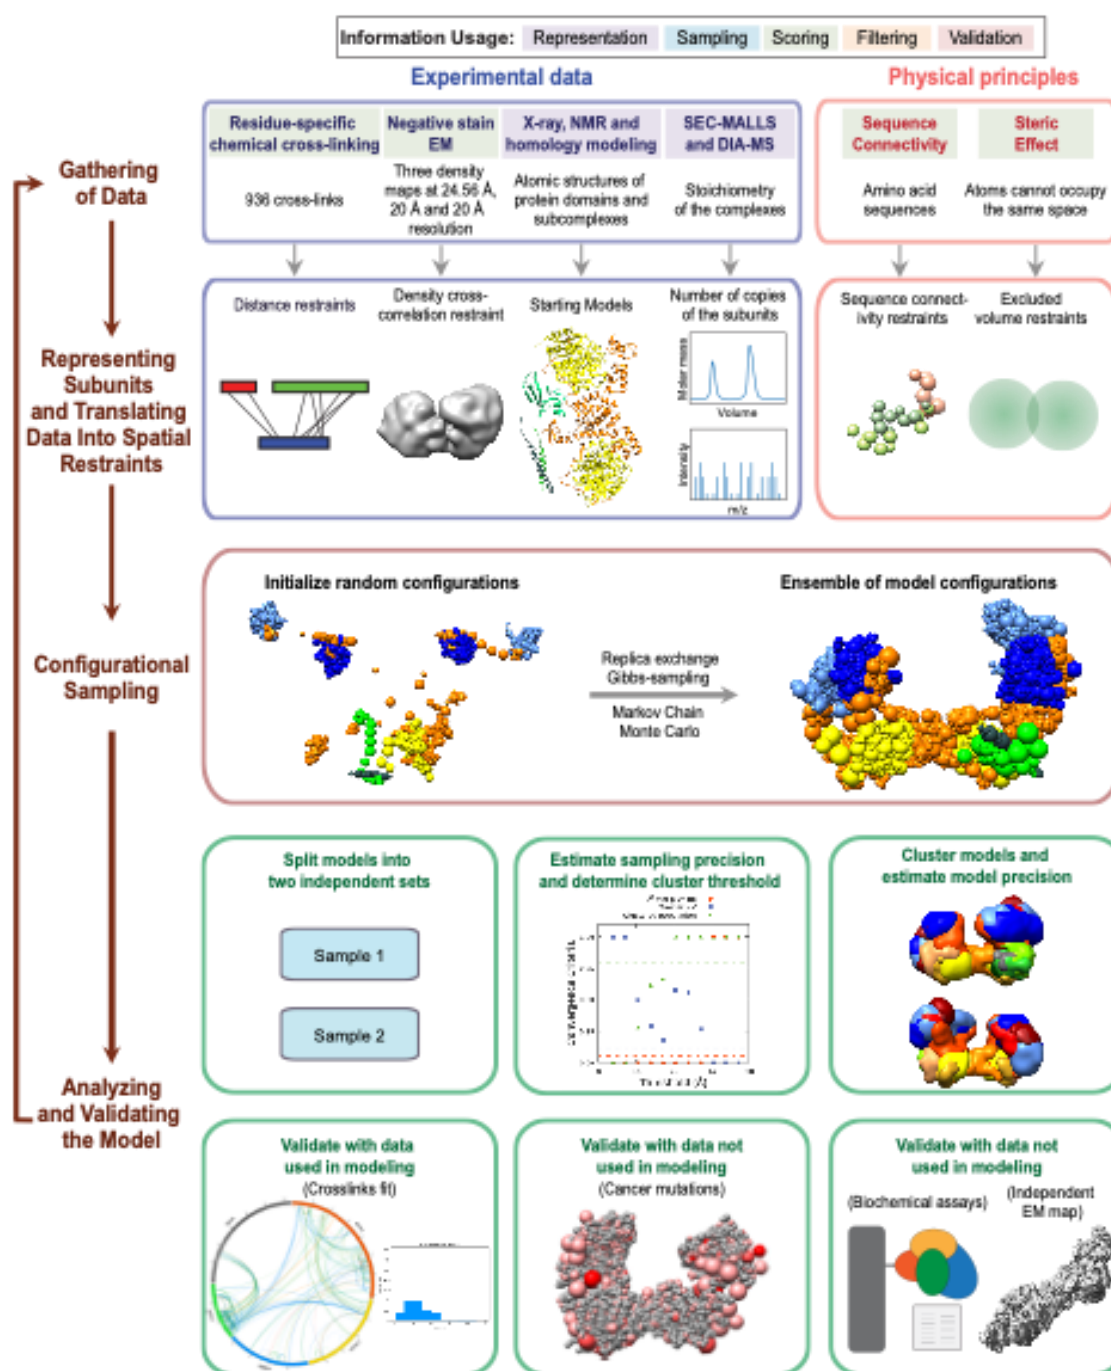

141

142 **Results**

Fig. 1 Integrative structure determination of NuRD sub-complexes Schematic describing the workflow for integrative structure determination of NuRD sub-complexes. The first row describes the input information. The second-row details how data is used to encode spatial restraints. The third row mentions the sampling method, and the last two rows illustrate the analysis and validation protocol. The background colors of the input information show the stage of modeling in which the information is used, as shown in the legend at the top.

Integrative modeling workflow

The integrative modeling of the MHR, MHM, and NuDe complexes proceeded in four stages (Fig. 1, Material and Methods) (Alber et al., 2007; Rout and Sali, 2019; Russel et al., 2012). The modeled NuRD proteins (subunits), their domains, their representations, and the number of copies in the modeled complexes are shown (Fig. S1A-S1C). The stoichiometry of the modeled proteins was informed by DIA-MS and SEC-MALLS experiments (Fig. S1C) (Low et

5

156 al., 2020). Regarding paralogs, a single representative for each protein was chosen for this
157 work for simplicity, namely MTA1, HDAC1, RBBP4, MBD3 and GATAD2A (Fig. S1A).
158
159 We first represented each protein as a series of beads of sizes that depend on the degree of
160 knowledge of the structure (and can vary throughout the sequence). Protein domains with
161 known atomic structures (such as the MTA1-HDAC1 dimer) were represented at 1 and 10
162 residues per bead and modeled as rigid bodies, whereas domains without known structure
163 (such as the MBD3^{IDR}) were coarse-grained at 30 residues per bead and modeled as flexible
164 strings of beads (Fig. S1A-S1B). Data from chemical crosslinking combined with mass
165 spectrometry (XL-MS) were used to restrain the distance between cross-linked residues.
166 Negative-stain EM maps were used to restrain the shape of the complexes (Low et al., 2020).
167
168 The simulations started with randomized configurations for the rigid bodies and flexible beads.
169 Over 40 million models per complex were sampled using a Monte Carlo approach (Replica
170 Exchange Gibbs Sampling MCMC; Materials and Methods). The models were scored based
171 on agreement with XL-MS and EM data, together with additional stereochemistry restraints
172 such as connectivity and excluded volume. For each complex, about 20,000 models that
173 sufficiently satisfied the input information were selected for further analysis (Saltzberg et al.,
174 2021).
175
176 These models were clustered based on structural similarity and the precision of the clusters
177 was estimated (Fig. S3-S5) (Saltzberg et al., 2019, 2021; Viswanath et al., 2017b). The quality
178 of the models was assessed by fit to input data (Fig. S6-S8), as well as data not used in
179 modeling, such as independent cryo-EM maps (Millard et al., 2020), published biochemical data
180 (Desai et al., 2015; Millard et al., 2020; Pflum et al., 2001; Zhang et al., 1999) and human
181 cancer-associated mutations (COSMIC) (Table S1) (Forbes et al., 2006). The resulting
182 integrative models were visualized in two ways - a representative bead model and a localization
183 probability density map, and represented in UCSF Chimera and ChimeraX (Pettersen et al.,
184 2021, 2004). The bead model represents the centroid of the major cluster, whereas the
185 localization probability density map represents all models in the major cluster, by specifying the
186 probability of a voxel (3D volume unit) being occupied by a bead in the set of superposed cluster
187 models.
188

189 **MHR**
190 First, to support the integrative modeling of the MHR complex, an *ab initio* 3D EM map for the
191 MHR complex was produced by further analysis of the MHR 2D class averages reported in a
192 previous study (Low et al., 2020). Integrative modeling of the 2:2:4 MHR complex produced
193 effectively a single cluster of models (85% of a total of 15200 models) with a model precision
194 of 27 Å; model precision is the average RMSD between the cluster centroid and models in the
195 cluster (Fig. S3). The models fit very well to the input data as measured by the EM and crosslink
196 scores. 98% of the input crosslinks were satisfied within their uncertainty (Fig. S6). An adipic
197 acid dihydrazide (ADH) / bis(sulfosuccinimidyl)suberate - disuccinimidyl suberate (BS3DSS) /
198 dimethoxy triazinyl methyl-morpholinium chloride (DMTMM) crosslink is violated if the
199 corresponding cross-linked beads are greater than 35 / 35 / 25 Å apart in all models in the
200 cluster. The cross-correlation between the localization probability density map for the models
201 in the major cluster and the input EM map was 0.74, indicating the fit to EM is reasonable but
202 not too high. This could partly be due to unoccupied density in the lobes of the experimental
203 EM map.
204

205 Surprisingly, the representative bead model from the dominant cluster (cluster centroid model)
206 shows the C-terminal half of the two MTA subunits (MTA1$^{432\text{-}715}$) crossing over (brown and
207 orange MTAs, Fig. 2A, Movie M1). Integrative models of the MHR complex created in the
208 absence of the EM map also showed the MTAs crossing over (Fig. S9).

210 The MTA1^{BAH} domain (MTA1$^{1\text{-}164}$) is positioned distal to the MTA1 dimerization interface
211 (MTA1$^{200\text{-}290}$, MTA1^{dimer}), consistent with its position in an independent EM map (Fig. 2B, Fig.
212 2C) (Millard et al., 2020). It is proximal to the HDAC1 active site and might regulate HDAC1
213 activity (Fig. 2A). This conclusion is consistent with histone deacetylation assays in which MTA1
214 was shown to modulate HDAC1 deacetylase activity in NuRD (Zhang et al., 1999). Further, for
215 one of the MTAs, the MTA1^{BAH} is located near an RBBP4 (Fig. 2A, Fig. 2B); MTA1^{BAH} proximity
216 to RBBP4 was also indicated in an independent cryo-EM map (Millard et al., 2020). Finally,
217 MTA1^{BAH} is also proximal to the MTA1^{mid} region (MTA1$^{334\text{-}431}$) containing the predicted helix (H)
218 and zinc finger regions (ZF) (Fig. 2B, Fig. 2C).

220 The MTA1^{mid} region is juxtaposed between MTA1^{dimer} and the MTA1^{BAH} domain (Fig. 2B). In
221 contrast, in a previous crosslink-based MHR model (Low et al., 2020), MTA1^{mid} was proximal
222 to the MTA1^{BAH} domain and distal from the MTA1^{dimer}. The MTA1 C-terminus (MTA1^{C}; *i.e.*,
223 MTA1$^{692\text{-}715}$) shows considerable conformational heterogeneity and is co-located with MTA1^{USR}
224 (MTA1$^{547\text{-}669}$), the MTA1 disordered region between the R1 and R2 RBBP4 binding regions
225 (Fig. 2B, Movie M1). Overall, many MTA1 domains in the MHR model, such as MTA1^{BAH}
226 domain, MTA1^{mid}, and MTA1^{C}, are exposed and could interact with nucleosomal DNA and/or
227 other proteins.

229 The HDAC1 C-terminus (HDAC1^{C}; *i.e.*, HDAC1$^{377\text{-}482}$) interacts with the MTA1^{BAH} domain (Fig.
230 2B). Although it has been shown that the MTA1-HDAC1 dimer can form in the absence of
231 MTA1^{BAH} (Millard et al., 2013), this additional interaction between MTA1 and HDAC1 could be
232 functionally important. Consistent with this possibility, mutations in HDAC1^{C} (Δ391-482, S421A,
233 S423A, E426A) have been known to disrupt binding to NuRD subunits (Pflum et al., 2001).
234 There are also post-translational modifications in the HDAC1 tail that might modulate its
235 interaction with MTA1 (Pflum et al., 2001; Rathert et al., 2008).

237 Both the MTA1^{R1}-RBBP4 units are located between the two lobes in the EM map, with one
238 complex in the front and the other at the back (dark blue beads and densities, Fig. 2A-2C). On
239 the other hand, the MTA1^{R2}-RBBP4 complexes are located in separate lobes (light blue beads
240 and densities, Fig. 2A-2C). The densities of RBBP4 are spread out, indicating its localization in
241 MHR is imprecise (Fig. 2B, Movie M1). This is consistent with the structural heterogeneity
242 observed in 2D class averages of the MHR EM data (Low et al., 2020). This flexibility could
243 facilitate RBBP4 interactions with transcription factors and histones.

Fig. 2 Integrative model of the MTA1-HDAC1-RBBP4 (MHR) complex A. Representative bead model from the most populated cluster of integrative models for the MHR complex, shown with the MHR EM map. The model is colored by subunit. For MTA1, the two copies are shown in different colors (brown and orange) in panels A and C, to illustrate the crossover. The HDAC1 active site is shown in red. B. Localization probability density maps showing the position of different domains/subunits in the cluster. The map specifies the probability of any volume element being occupied by a domain in the ensemble of superposed models from the cluster. The domain densities are colored according to Fig. S1. These maps are contoured at ~10% of their respective maximum voxel values. C. Schematic representation of the integrative model of the MHR complex. See also Figs. S1, S3, S6, and Movie M1.

MHM

Integrative modeling of the 2:2:2 MHM complex resulted in a major cluster containing 60% of 21960 models. The model precision was 24 Å and 99% of the input crosslinks were satisfied (Fig. S4, Fig. S7). The cross-correlation between the localization probability density map for the models in the major cluster and the input EM map was 0.90.

8

260

261 First, in a control run, where MHM was modeled as a 2:2:1 complex with a single copy of MBD3,
262 we observed two symmetric MBD3 binding sites (Fig. S10). However, our 2:2:2 MHM model
263 shows that the two copies of MBD3 bind asymmetrically on the MTA1-HDAC1 dimer (Fig. 3A-
264 3C, Movie M2). One MBD3 localizes exclusively to one end of the MTA1-HDAC1 dimer, making
265 contacts predominantly with a single MTA1 and HDAC1 (pink MBD3, Fig. 3C), whereas the
266 other MBD3 is more spread out and interacts with both copies of MTA1 and HDAC1 (green
267 MBD3, Fig. 3C).

268

269 In our models, both the copies of MBD3^{MBD} localize close to the MTA1^{BAH} domain, which is
270 similar to the location observed for MBD2^{MBD} in an independent cryo-EM map of a 2:2:1
271 MTA1:HDAC1:MBD2 complex (Fig. 3A-3C) (Millard et al., 2020). Although there are two
272 MBD3s in our models, only a single MBD3^{IDR} localizes to the MTA1 dimerization interface,
273 MTA1^{dimer} (green MBD3, Fig. 3D-3E). This localization of MBD3^{IDR} is consistent with its
274 previously predicted localization from the crosslinks-based model (Low et al., 2020) and the
275 localization of MBD2^{IDR} based on cryo-electron microscopy (Millard et al., 2020). It is also
276 supported by two separate mutagenesis and co-immunoprecipitation studies, one of which
277 showed that MBD2^{IDR} was essential for binding to the MTA1-HDAC1 dimer (Desai et al., 2015),
278 while the other showed that MTA1^{dimer} was essential for its interaction with MBD2 (Millard et al.,
279 2020). It is known that MBD3 binding in NuDe/NuRD is asymmetric; although there are two
280 symmetric MBD3 binding sites, there is a single MBD3 in these complexes (Low et al., 2020).
281 It is possible that a single MBD3 is present in NuDe/NuRD since a single MBD3^{IDR} can bind to
282 the MTA1^{dimer} (see also Discussion).

283

284 For both MBDs, the MBD3^{MBD} domain is proximal to the MTA1^{BAH} domain, and the MBD3^{IDR} is
285 close to the MTA1^{mid} region (Fig. 3B, Fig. 3E). The MBD3^{CC}-GATAD2^{CC} coiled-coil domain is
286 exposed. Finally, in a small minority of models, both MBDs are localized together on the same
287 side of the MTA1^{dimer}; however, we believe this latter configuration is possibly due to numerous
288 intra-MBD3 crosslinks (Movie M2).

Fig. 3 Integrative model of the MTA1^N-HDAC1-MBD3^{GATAD2CC} (MHM) complex A. Representative bead model from the major cluster of analyzed integrative models for the MHM complex, with the corresponding EM map (EMD-21382) (Low et al., 2020), colored by subunit. The domains of the two MBD3s are shown in shades of pink and green respectively. B. Localization probability density maps showing the position of different domains in the ensemble of models from the cluster. The domain densities are colored according to Fig S1. C. The same density maps as B (front view), showing the two MBDs in pink and green respectively, illustrating that they localize differently on the MTA1-HDAC1 dimer. The density maps of MTA1^{mid} and GATAD2^{cc} were omitted for clarity. D. The density maps of the two MBD3^{IDR} domains on the MTA1-HDAC1 dimer. Almost all the maps are contoured at 20% of their respective maximum voxel values (GATAD2 maps are contoured at 27% whereas MBD3^{IDR} maps are contoured at 10%). E. Schematic representation of the integrative model of the MHM complex. Note that MTA1^{mid} in this model corresponds to MTA1$^{334-431}$. See also Figs. S1, S4, S7, and Movie M2.

NuDe

302 Although the NuDe complex contains full-length GATAD2, due to the lack of information on full-
303 length GATAD2, we modeled only the GATAD2 region that forms a coiled-coil with MBD3.
304 Integrative modeling of the NuDe complex resulted in effectively a single cluster (99% of 21632
305 models). The model precision was 35 Å and 99% of the input crosslinks were satisfied (Fig. S5,
306 Fig. S8). The cross-correlation between the localization probability density map for the models
307 in the major cluster and the input EM map was 0.88.
308

309 In contrast to our MHM model, where one MBD3 was proximal to the MTA1^{SANT} domain, MBD3
310 in NuDe localizes precisely to one end of the MTA1-HDAC1 dimer, away from the MTA1^{SANT}
311 domain. It is juxtaposed next to the MTA1^{BAH} and MTA1^{mid} domains, as well as HDAC1 (Fig.
312 4A-4C, Movie M3). An independent cryo-EM map of MTA1$^{1-546}$-HDAC1-MBD2-RBBP4 also
313 showed that MBD3 was proximal to MTA1^{BAH} and MTA1^{dimer} (Millard et al., 2020). It is possible
314 that the presence of GATAD2 sterically precludes MBD3 from occupying the MTA1 dimerization
315 interface (see also Discussion).
316

317 From protein-protein distance maps of the cluster, HDAC1$^{60-100}$ and MTA1^{BAH} are most proximal
318 to MBD3 (Fig. S11A, S11B). MBD3^{CC}-GATAD2^{CC} is exposed. The MBD3^{MBD} domain is buried,
319 consistent with the failure of MBD3 to bind DNA in NuRD noted in immuno-precipitation
320 experiments (Fig. 4A-4C) (Zhang et al., 1999). Interestingly, several nucleosome-interacting
321 domains such as MTA1^{BAH} and MTA1^{ZF} are co-localized in the NuDe model (Fig. 4A-4C).
322

323 Similar to the MHR models, the HDAC1^{C} domain is proximal to MTA1^{BAH} (Fig. S11C).
324 Mutagenesis and co-immunoprecipitation studies have shown that HDAC1^{C} makes critical
325 interactions with NuRD subunits (Pflum et al., 2001). In contrast to the MHR models which
326 showed crossover of MTAs, the two MTAs are well-separated in NuDe (Fig. 4A-4C). The
327 localization of RBBPs is also more precise in NuDe than in MHR (Fig. S12).

11

Fig. 4 Integrative model of the nucleosome deacetylase (NuDe) complex A. Representative bead model from the dominant cluster of integrative models for the NuDe complex, with the corresponding EM map (EMD-22904) (Low et al., 2020), colored by subunit. B. Localization probability density maps showing the position of different domains in the ensemble of models from the cluster. The domain densities are colored according to Fig S1. Maps are contoured at ~10% of their respective maximum voxel values. C. Schematic representation of the integrative model of the NuDe complex. See also Figs. S1, S5, S8, S11, and Movie M3.

Mapping COSMIC mutations

We next consulted the COSMIC (Catalogue of Somatic Mutations in Cancer) database for somatic, confirmed pathogenic, point mutations of the NuRD subunits, MTA1, HDAC1, RBBP4, and MBD3 (Forbes et al., 2006). In total, 356 point mutations were identified and mapped onto the cluster of NuDe integrative models (Methods, 4.5 COSMIC data analysis). Analysis of these mutations revealed that 74% of mutations mapped to protein-protein interfaces within NuDe; for this analysis, a mutation was considered to be at an interface if the average distance of the corresponding residue to a residue in an interacting protein is less than 10 Å. 29% of the mapped mutations were located in previously uncharacterized binding interfaces predicted by our model, such as MBD3-MTA1^{BAH}, MBD3-HDAC1$^{60-100}$, and HDAC1^{C}-MTA1^{BAH}, consistent with the idea that these interfaces are important for NuRD function (Fig. 5, Fig. S13, Table S1).

349 Mutations at protein-protein interfaces could alter protein-protein interactions, reducing the
350 stability of the complex, thereby leading to pathogenicity. Moreover, 19% of all mutations
351 mapped to exposed regions that are known to bind to nucleosomes and transcription factors,
352 such as the HDAC1 active site and RBBP4 H3 interaction site (Fig. 5, Fig. S13, Table S1).
353 These mutations could impair NuRD binding to partners such as nucleosomes or transcription
354 factors, contributing to the pathogenesis of disease. Of the 19% that map to exposed regions,
355 more than half (57%) of the mutations map to regions of unknown structure (regions for which
356 no experimental structure or reliable model is available), such as MTA1^{USR} and MBD3^{IDR} (Fig.
357 5, Table S1). The functional significance of these mutations is therefore difficult to predict, but
358 could indicate that these regions of unknown structure also have important roles in protein
359 stability, regulating interactions between NuRD subunits, or interactions with binding partners
360 of NuRD. An important consideration for all these disease-causing mutations is that many of
361 the NuRD subunits function in cellular contexts independent of other NuRD subunits, and so in
362 some cases, these mutations may be rationalised in the context of other functional roles.

363
364 **Fig. 5 COSMIC mutations mapped onto the NuDe integrative model.** Somatic pathogenic point mutations from
365 the COSMIC database (Forbes et al., 2006) mapped onto the representative bead model of the NuDe complex
366 (Fig. 4A). A. Mutations of residues that map to previously undescribed protein-protein interfaces within our model.
367 Residues from two proteins are at an interface if the average distance between their corresponding bead surfaces
368 is less than 10 Å in the cluster of NuDe integrative models. B. Mutations on residues that map to exposed binding
369 sites between modeled proteins and known binding partners. A bead is colored according to the maximum number
370 of mutations on any residue in the bead, according to the legend. Representative mutations are labeled in both A.
371 and B. See also Table S1 and Fig. S13.

372

373 **Docking the nucleosome**
374 We next attempted to dock the CHD4-nucleosome structure (Farnung et al., 2020) into the cleft
375 in the NuDe structure between the MTA1 C-terminal arms (Fig. 6). Although there are limitations
376 to this docking (for example, it is a coarse placement, lacks histone tail densities, and binding
377 sites for the nucleosome outside the cleft might also exist), this positioning of the nucleosome
378 indicates its size complementarity to the integrative model, further corroborating the latter. This

13

379 placement allows for the histone H3 and H4 tails to be located towards the HDAC1 active site.
380 It also accommodates the known interactions between the RBBPs and the histone H3 (Fig. 6).
381 The partial CHD4 structure is exposed. MTA1^{mid}, which contains the zinc finger, can also
382 potentially interact with the nucleosome in this position. Finally, MBD3 does not interact with
383 the nucleosome, since MBD3^{MBD} is buried in NuDe (Fig. 4A-4C), consistent with MBD3 in NuRD
384 failing to bind DNA in immuno-precipitation experiments (Zhang et al., 1999).
385
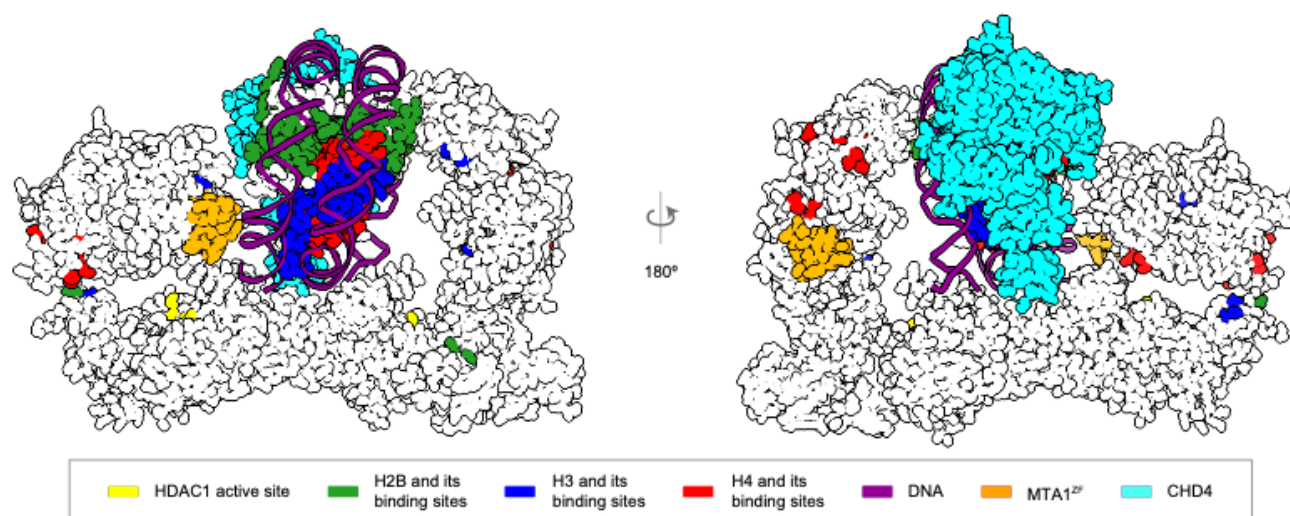

386
387
388 **Fig. 6 Integrative model of NuDe complex with the nucleosome** The CHD4-nucleosome structure (Farnung et
389 al., 2020) is placed in the cleft of the NuDe integrative model. The regions with known atomic structure are shown
390 in the NuDe integrative model from Fig. 4A. Nucleosome proteins/DNA and the corresponding NuDe subunit
391 residues they are known to bind to, are depicted in the same color, as given by the legend.

Discussion

393 Here, we obtained structural models of the MTA1-HDAC1-RBBP4 (MHR), MTA1^{N}-HDAC1-
394 MBD3 (MHM), and MTA1-HDAC1-RBBP4-MBD3-GATAD2 (NuDe) complexes using Bayesian
395 integrative modeling. The approach allowed us to combine all available structural information,
396 including data from SEC-MALLS, DIA-MS, chemical crosslinking mass spectrometry (XLMS),
397 negative stain EM, X-ray crystallography, NMR spectroscopy, secondary structure, and
398 homology predictions (Methods, Fig. 1) (Alqarni et al., 2014; Connelly et al., 2006; Cramer et
399 al., 2014; Gnanapragasam et al., 2011; Low et al., 2020; Millard et al., 2016, 2013; Söding et
400 al., 2005; Tjandra et al., 1997). The models were corroborated by independent cryo-EM maps,
401 enzyme assays, mutagenesis, co-immunoprecipitation studies, and the mapping of cancer
402 mutations (Fig. 5, Fig. S13, Table S1) (Desai et al., 2015; Forbes et al., 2006; Millard et al.,
403 2020; Pflum et al., 2001; Zhang et al., 1999). Importantly, our approach allowed us to localize
404 regions of unknown structure, for *e.g.*, HDAC1^{C} and MBD3^{IDR}, in context of regions of known
405 structure, for *e.g.*, the MTA1-HDAC1 dimer, resulting in the most complete structural
406 characterization of these NuRD sub-complexes so far.
407

NuDe complex is more ordered than MHR

409 A comparison of MTA1 and RBBP4 in the MHR and NuDe models suggests that these subunits
410 are more conformationally heterogenous in MHR, as shown by the broader localization
411 probability densities for the C-terminal half of MTA1 and RBBPs in MHR (volume enclosed by
412 the corresponding maps = 1120 nm^3) compared to NuDe (volume enclosed = 883.6 nm^3) (Fig.
413 S12). Also, the cross-correlation of the MHR localization probability density to the

14

414 corresponding EM map is lower than that of NuDe, indicating higher heterogeneity for the
415 former. This indicates that the MHR is initially dynamic and the presence of MBD3-GATAD2
416 possibly makes it less dynamic.
417

MBD3^{IDR} – MTA1^{dimer} interaction

419 In our MHM models, one MBD3^{IDR} is near the MTA1^{dimer}, consistent with the previously
420 predicted localization of MBD3^{IDR} based on chemical crosslinks (Low et al., 2020) and MBD2^{IDR}
421 based on a cryo-electron density map (Fig. 3C-3E) (Millard et al., 2020). Two separate
422 mutagenesis and co-immunoprecipitation studies have shown that the MBD^{IDR} and the MTA1
423 dimerization interface are each essential for MBD2 interaction with the MTA1-HDAC1 dimer
424 (Desai et al., 2015; Millard et al., 2020). Despite the corresponding region of MBD2 being
425 disordered in solution (Desai et al., 2015), MBD3$^{125-175}$ is predicted to be ordered based on
426 PONDR® analysis (Fig. S14) (http://www.pondr.com) (Romero et al., 2001, 1997). Because this
427 region is well conserved across species (Cramer et al., 2017), it is likely that it becomes ordered
428 upon binding, similar to the region of MTA1 that winds irregularly across the surface of HDAC1
429 (MTA1$^{165-226}$). Further, the crosslinks between MBD3^{IDR} and MTA1 involve a loop (MTA1$^{229-236}$)
430 of the MTA1^{dimer} that is not visible in the MTA1-HDAC1 crystal structure. It is possible that this
431 region of MTA1 may also become ordered upon binding MBD3.

432
Fig. 7 Bind-and-shift model of MBD3 binding to MHR The figure shows two stages of MBD3 assembly in NuRD.
A. In the first stage, the MTA1 dimerization interface is accessible for MBD3^{IDR} to bind. B. In the second stage,
upon binding, MBD3 recruits GATAD2 and the chromatin remodeling module and shifts to one end of the MTA1-
HDAC1 dimer. GATAD2 localizes near MTA1dimer, precluding a second MBD3 from binding to it.

Bind-and-shift model of MBD3 binding to MHR

The stoichiometry of MBD3 in NuRD is intriguing. The MHM complex has two copies of MBD3, while a single MBD3 is seen in the NuDe and NuRD complexes (Low et al., 2020). Based on our integrative models, we propose a two-stage mechanism to explain the asymmetric binding of MBD3 in NuRD (Fig. 7).

In the first stage (Fig. 7A), the C-terminal arms of MTA1 in MHR are heterogenous and adopt a range of configurations including an extended, open state (Millard et al., 2020) and crossed-over state (Fig. 2, MHR models). In the open state, the MTA1 dimerization interface is accessible for MBD3^{IDR} to bind. This interaction of MBD3^{IDR} with the MTA1^{dimer} is also observed in a cryo-EM study on MTA1:HDAC1:MBD2 and is known to be critical for MBD recruitment to the deacetylase module (Fig. 3, MHM models) (Desai et al., 2015; Millard et al., 2020).

In the second stage (Fig. 7B), upon binding to MTA1^{dimer}, MBD3 recruits GATAD2 and the chromatin remodeling module and shifts to one end of the MTA1-HDAC1 dimer (Fig. 4, NuDe models). In this state, GATAD2 localizes near MTA1^{dimer}, precluding a second MBD3 from binding to it. Although we did not model full GATAD2 in NuDe due to unavailability of structures and crosslinks involving the protein, the proximity of CHD4, and hence GATAD2, to the MTA1^{dimer} in our coarse nucleosome docking supports this idea (Fig. 6). This possibly explains how GATAD2 introduces asymmetry of MBD3 binding in NuRD. Moreover, upon binding the chromatin remodeling module, the C-terminal arms of MTA1 with the RBBPs are less heterogenous and adopt a closed configuration (Fig. 4, Fig. S12).

The novel NuRD protein interfaces predicted by our model need to be confirmed by future experiments. High-resolution structures of regions such as MBD3^{IDR} will delineate their roles in NuRD. Ultimately, a complete atomic characterization of the NuRD complex will aid in understanding NuRD-mediated regulation of gene expression.

Materials and Methods

Integrative modeling

The integrative structure determination of the NuRD sub-complexes proceeded through four stages (Fig. 1) (Alber et al., 2007; Rout and Sali, 2019; Russel et al., 2012). The modeling protocol (i.e., stages 2, 3, and 4) was scripted using the Python Modeling Interface (PMI) package, a library for modeling macromolecular complexes based on open-source Integrative Modeling Platform (IMP) package, version 2.13.0 (https://integrativemodeling.org) (Russel et al., 2012). The current procedure is an updated version of previously described protocols (Ganesan et al., 2020; Gutierrez et al., 2020; Kim et al., 2018; Saltzberg et al., 2019, 2021; Viswanath et al., 2017a; Webb et al., 2018). Files containing the input data, scripts, and output results are publicly available at https://github.com/isblab/nurd .

Stage 1: Gathering data

The stoichiometry and isoforms of subunits were based on DIA-MS and SEC-MALLS experiments (Fig. S1) (Low et al., 2020). Known atomic structures were used for the MTA1-HDAC1 dimer, MTA1^{R1} and MTA1^{R2} domains in complex with RBBP4, and MBD domain of MBD3 (Fig. S1) (Alqarni et al., 2014; Cramer et al., 2014; Millard et al., 2016, 2013). The MTA1^{BAH} domain, MTA1^{H}, MTA1^{ZF}, and MBD3^{CC}-GATAD2A^{CC} structures were homology-modeled based on the structures of related templates (Fig. S1A) (Connelly et al., 2006; Gnanapragasam et al., 2011; Tjandra et al., 1997).

16

487

488 The shapes of the complexes were based on 3D negative-stain EM maps; MHR: to be
489 deposited (24.56 Å), MHM: EMD-21382 (20 Å), and NuDe: EMD-22904 (20 Å) (Low et al.,
490 2020). The negative-stained EM map for the MHR complex was produced by further analysis
491 of data reported in a previous study (Fig. S2) (Low et al., 2020). 25,155 particle images were
492 subjected to multiple rounds of 2D classification in CryoSparc (Punjani et al., 2017), following
493 which an *ab initio* 3D reconstruction was obtained and refined by homogenous 3D refinement.
494 The final map was produced from 13,299 particles and had an estimated resolution of ~25 Å
495 according to the FSC0.143 criterion.

496

497 Chemical crosslinks informed the relative localization of the NuRD subunits. A total of 936
498 crosslinks, including 877 BS3DSS (bis(sulfosuccinimidyl)suberate - disuccinimidyl suberate),
499 40 DMTMM (dimethoxy triazinyl methyl-morpholinium chloride), and 19 ADH (adipic acid
500 dihydrazide) crosslinks were used (Low et al., 2020). The models were validated by
501 independent EM maps (Millard et al., 2020), biochemical assays (Desai et al., 2015; Pflum et
502 al., 2001; Zhang et al., 1999), and human cancer-associated mutations on NuRD proteins
503 (Forbes et al., 2006).

504

505 **Stage 2: Representing the system and translating data into spatial restraints**
506 The stoichiometry and representation of subunits is shown (Fig. S1). The domains with known
507 atomic structures were represented in a multi-scale manner with 1 and 10 residues per bead to
508 maximize computational efficiency. These domains were modeled as rigid bodies where the
509 relative distances between beads is constrained during sampling. In contrast, domains without
510 known structure were coarse-grained at 30 residues per bead and modeled as flexible strings
511 of beads.

512

513 We next encoded the spatial restraints into a scoring function based on the information
514 gathered in Stage 1, as follows:

515 (1) *Cross-link restraints:* The Bayesian cross-links restraint (Rieping et al., 2005) was used to
516   restrain the distances spanned by the cross-linked residues (Shi et al., 2014).

517 (2) *EM restraints:* The Bayesian EM density restraint was used to restrain the shape of the
518 modeled complexes and was based on the cross-correlation between the Gaussian Mixture
519 Model (GMM) representations of the NuRD subunits and the GMM representation of the
520 corresponding negative-stain EM density maps (Bonomi et al., 2019).

521 (3) *Excluded volume restraints*: The excluded volume restraints were applied to each bead,
522 using the statistical relationship between the volume and the number of residues that it covered
523 (Alber et al., 2007).

524 (4) *Sequence connectivity restraints*: We applied the sequence connectivity restraints, using a
525 harmonic upper distance bound on the distance between consecutive beads in a subunit, with
526 a threshold distance equal to twice the sum of the radii of the two connected beads. The bead
527 radius was calculated from the excluded volume of the corresponding bead, assuming standard
528 protein density (Shi et al., 2014).

529

Stage 3: Structural sampling to produce an ensemble of structures that satisfies the restraints

We aimed to maximize the precision at which the sampling of good-scoring solutions was exhaustive (Stage 4). The sampling runs relied on Gibbs sampling, based on the Replica Exchange Monte Carlo algorithm (Saltzberg et al., 2019, 2021). The positions of the rigid bodies (domains with known structure) and flexible beads (domains with unknown structure) were sampled.

The initial positions of the flexible beads and rigid bodies in all complexes were randomized, with one exception. For MHR, we were able to unambiguously dock the structure of the MTA1-HDAC1 core in the EM map, with the help of the previous EM map (EMD-3399) (Millard et al., 2016). Hence, the position of the corresponding rigid body was fixed throughout.

The Monte Carlo moves included random translations of individual beads in the flexible segments and rigid bodies (around 3.7 Å and 1.3 Å respectively). A model was saved every 10 Gibbs sampling steps, each consisting of a cycle of Monte Carlo steps that moved every bead and rigid body once.

The sampling produced a total of 40 million MHR, 48 million MHM, and 80 million NuDe integrative models.

Stage 4: Analysing and validating the ensemble of structures and data

The sampled models were analysed to assess sampling exhaustiveness and estimate the precision of the structure, its consistency with input data and consistency with data not used in modeling. The structure was further validated by experiments based on the predictions from the models. We used the analysis and validation protocol published earlier (Rout and Sali, 2019; Saltzberg et al., 2019, 2021; Viswanath et al., 2017b). Assessment began with a test of the thoroughness of structural sampling, including structural clustering of the models, estimating model precision, and visualizing the variability in the ensemble of structures using localization probability density maps (Viswanath et al., 2017b). The precision of a domain refers to its positional variation in an ensemble of superposed models. It can also be visualized by the localization probability density map for the domain. A localization probability density map specifies the probability of a voxel (3D volume unit) being occupied by a bead in a set of superposed models. The models and densities were visualized with UCSF Chimera and ChimeraX (Pettersen et al., 2021, 2004).

(1) *Determining good-scoring models*

Starting from the millions of sampled models, first, we selected models obtained after score equilibration and clustered them based on the restraint scores (Saltzberg et al., 2021). For further analysis, we considered 15200 MHR, 21960 MHM, and 21632 NuDe good-scoring models that satisfy the data restraints sufficiently well.

(2) *Clustering and structure precision*

We next assessed the sampling exhaustiveness and performed structural clustering (Saltzberg et al., 2019, 2021; Viswanath et al., 2017b). Integrative structure determination resulted in effectively a single cluster for all complexes, at a precision of 26.8 Å (MHR), 23.8 Å (MHM), and 34.6 Å (NuDe). The cluster precision is the bead RMSD from the cluster centroid model averaged over all models in the cluster (Viswanath et al., 2017b).

18

579   (3) *Fit to input information*
580 The dominant clusters from each modeled NuRD sub-complex satisfied over 95% of all the
581 BS3DSS, ADH, and DMTMM crosslinks used; a crosslink is satisfied by a cluster of models if
582 the corresponding Cα-Cα distance in any model in the cluster is less than 35Å, 35Å, 25Å for
583 BS3DSS, ADH, and DMTMM crosslinks respectively. The agreement between the models and
584 the corresponding EM maps was computed by calculating the cross-correlation of the combined
585 localization probability densities of all subunits for the major cluster with the experimental EM
586 map using the *fitmap* tool in UCSF Chimera (Fig. 2-4) (Pettersen et al., 2004). The remainder
587 of the restraints are harmonic, with a specified standard deviation. The cluster generally
588 satisfied the excluded volume and sequence connectivity restraints. A restraint is satisfied by a
589 cluster of models if the restrained distance in any model in the cluster (considering restraint
590 ambiguity) is violated by less than 3 standard deviations, specified for the restraint. Most of the
591 violations are small, and can be rationalized by local structural fluctuations, coarse-grained
592 representation of the model, and/or finite structural sampling.
593
594   (4) *Fit to data not used in modeling*
595 The MHR integrative models were supported by histone deacetylation assays, mutagenesis,
596 and co-immunoprecipitation, showing that MTA1 and the HDAC1^C regulate HDAC1
597 deacetylase activity and NuRD assembly (Pflum et al., 2001; Zhang et al., 1999). The
598 localization of domains such as MTA1^{BAH} and RBBP4 were validated by their consistency with
599 independently determined cryo-EM maps (Millard et al., 2020).
600
601 The MHM integrative models were supported by independent cryo-EM maps of the complex
602 showing similar localizations for MBD2^{MBD} and MTA1^{BAH} (Millard et al., 2020). The MBD3^{IDR}-
603 MTA1^{dimer} interaction was also supported by two separate mutagenesis and co-
604 immunoprecipitation studies (Desai et al., 2015; Millard et al., 2020).
605
606 The NuDe integrative models were corroborated by immunoprecipitation experiments showing
607 that the MBD domain of MBD3 is buried in NuRD (Zhang et al., 1999). They were also
608 supported by independent cryo-EM maps showing that MBD3 is proximal to MTA1^{BAH}, and
609 biochemical assays showing the importance of HDAC1^C interactions in NuRD (Millard et al.,
610 2020; Pflum et al., 2001). The mapping of cancer mutations to protein-protein interfaces in the
611 NuDe model also supported them (Fig. 5, Fig. S13, Table S1) (Forbes et al., 2006).
612
613   *4.1 Mapping COSMIC mutations*
614 We obtained a total of 356 somatic, confirmed pathogenic, point mutations for the modeled
615 NuRD subunits (MTA1, HDAC1, RBBP4, MBD3) from the COSMIC (Catalogue of Somatic
616 Mutations in Cancer) database (Forbes et al., 2006). For each subunit, point mutations were
617 selected from search results based on the presence of census genes and correct
618 documentation of current structures. To ensure the mutations studied significantly affect the
619 function, folding, and protein-protein interaction of the protein, the "confirmed pathogenic" and
620 "somatic" filters were applied in all cases.
